Experiment No. 2
Analyze the Titanic Survival Dataset and Apply appropriate
Regression Technique
Date of Performance:
Date of Submission:

Department of Computer Engineering

Aim: Analyze the Titanic Survival Dataset and Apply appropriate Regression Technique.

Objective: Able to perform various feature engineering tasks, apply logistic regression on the given dataset and maximize the accuracy.

Theory:

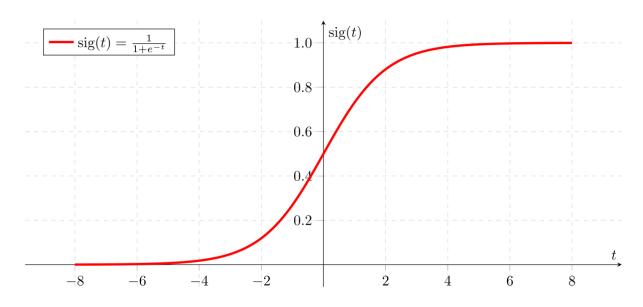

Logistic Regression was used in the biological sciences in early twentieth century. It was then used in many social science applications. Logistic Regression is used when the dependent variable(target) is categorical and is binary in nature. In order to perform binary classification the logistic regression techniques makes use of Sigmoid fuction.

For example,

To predict whether an email is spam (1) or (0)

Whether the tumor is malignant (1) or not (0)

Consider a scenario where we need to classify whether an email is spam or not. If we use linear regression for this problem, there is a need for setting up a threshold based on which classification can be done. Say if the actual class is malignant, predicted continuous value 0.4 and the threshold value is 0.5, the data point will be classified as not malignant which can lead to serious consequence in real time.

Department of Computer Engineering

From this example, it can be inferred that linear regression is not suitable for classification problem. Linear regression is unbounded, and this brings logistic regression into picture. Their value strictly ranges from 0 to 1.

Dataset:

The sinking of the Titanic is one of the most infamous shipwrecks in history.

On April 15, 1912, during her maiden voyage, the widely considered "unsinkable" RMS Titanic sank after colliding with an iceberg. Unfortunately, there weren't enough lifeboats for everyone onboard, resulting in the death of 1502 out of 2224 passengers and crew.

While there was some element of luck involved in surviving, it seems some groups of people were more likely to survive than others.

In this challenge, we ask you to build a predictive model that answers the question: "what sorts of people were more likely to survive?" using passenger data (ie name, age, gender, socio-economic class, etc).

Variable	Definition	Key
survival	Survival	0 = No, 1 = Yes
pclass	Ticket class	1 = 1st, 2 = 2nd, 3 = 3rd
sex	Sex	
Age	Age in years	
sibsp	# of siblings / spouses aboard the Titanic	
parch	# of parents / children aboard the Titanic	
ticket	Ticket number	
fare	Passenger fare	
cabin	Cabin number	
embarke d	Port of Embarkation	C = Cherbourg, Q = Queenstown, S = Southampton

Vidyavardhini's College of Engineering & Technology Department of Computer Engineering

Variable Notes

pclass: A proxy for socio-economic status (SES)

1st = Upper, 2nd = Middle, 3rd = Lower

age: Age is fractional if less than 1. If the age is estimated, is it in the form of xx.5

sibsp: The dataset defines family relations in this way...,

Sibling = brother, sister, stepbrother, stepsister

Spouse = husband, wife (mistresses and fiancés were ignored)

parch: The dataset defines family relations in this way...

Parent = mother, father

Child = daughter, son, stepdaughter, stepson

Some children travelled only with a nanny, therefore parch=0 for them.

Code & Output:

```
import pandas as pd

df = pd.read_csv('TITANIC.csv')

df.head()
```

```
female = [[30, 1, 0, 1, 0, 0]]
model.predict(female)[0]

probability = model.predict_proba(female)[0][1]
print(f'Probability of survival: {probability:.1%}')
Probability of survival: 91.6%

male = [[60, 0, 1, 0, 0, 1]]
probability = model.predict_proba(male)[0][1]
print(f'Probability of survival: {probability:.1%}')
Probability of survival: 2.9%
```

Conclusion: The logistic regression model achieved an accuracy of 83.22% on the test set, demonstrating good performance in predicting Titanic survivors. The model's cross-validation score of approximately 78.57% indicates stability across different data splits. The confusion matrix reveals that the model has a higher rate of false negatives (incorrectly predicting survivors as non-survivors) than false positives. The classification report shows better precision and recall for non-survivors (class 0) than survivors (class 1), with an overall balanced performance reflected in the F1-scores.
